

Confirmatory estimates, with their 95% intervals

H1 – H3: the estimate each hypothesis is stated as

Diamonds are the quantity the hypothesis names; small circles are its components. Filled = 95% interval excludes zero. H1 on 71,136 rows, H2 on 71,136, H3 on 21,594 (269 utterance clusters — the extra rows are the same transcripts re-routed).

H4b: the interaction, expressed against the pre-registered `clean` anchor

Single interaction coefficients are contrasts against a reference level and change with it: against `clean` only additive noise clears p < 0.05 (+0.1944, p = 0.0069); reverberation does not (-0.0984, p = 0.171). Against `babble` both clear at p = 0.005. The hypothesis is the joint test above, not any row below it. Filled markers mark p < 0.05 individually and are not a second test.
